Lab 4

Python version:

Calculations:

Short Answers:

13) Variable elimination is exact: it reuses partial results instead of recomputing, so it stays fast on larger networks.

14) Appointment is directly linked to Train alone, and Train is known, so the value is read straight from the table.

16) Missing the appointment is a clue that a delay happened (P(delayed) rose from 0.213 to 0.52), and a delay is a clue for rain, so evidence travels up the arrows, step by step.

18) Strong evidence shifts beliefs a lot; weak evidence shifts them only a little, and here a delay is nearly as likely whether or not maintenance happened.
